

EIP 155: Intentional islanding of remote renewable networks for increased resilience in the face of climate threats

ENA Basecamp 2026

4th February 2026

What is Intentional Islanding?

What is it?

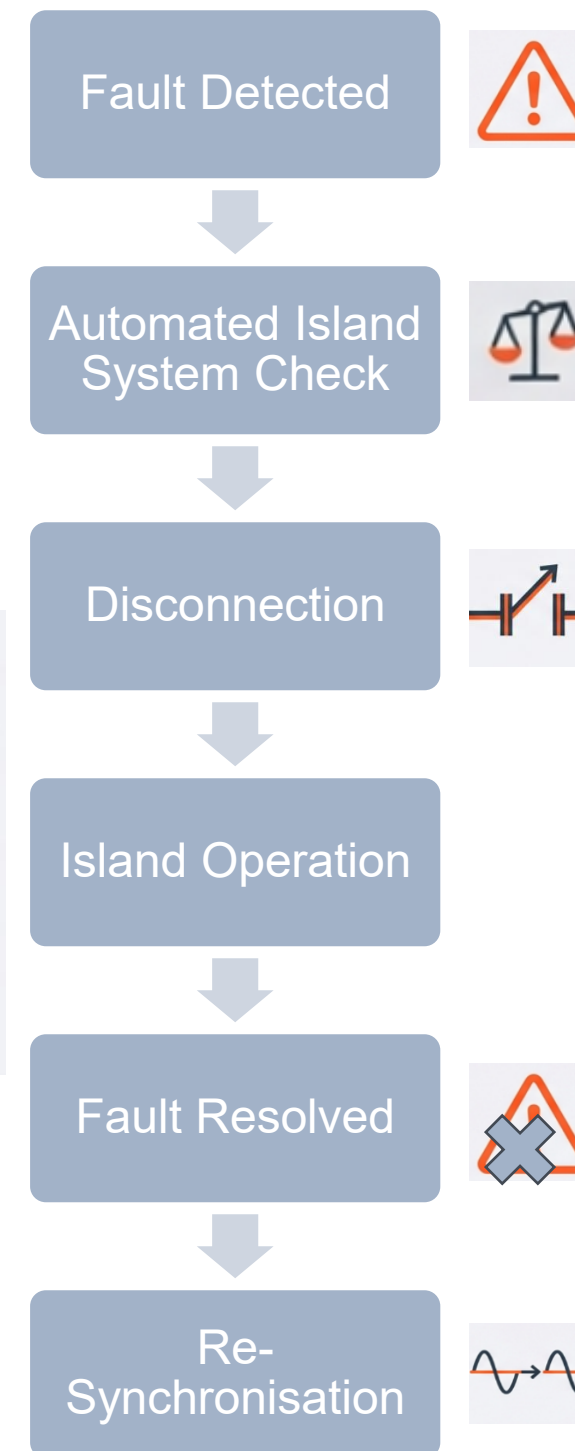

- Pre-planned, controlled separation from the transmission network
- Network Islands designed to be electrically self-sustaining for a period of time
- Activated during extreme events or restoration scenarios
- Distinct from uncontrolled system breakup

Analogy

A self-contained system like a diver's rebreather which contains all the necessary breathing apparatus in a closed loop.

Innovation Project

To model the network with intentional islanding to understand power flow behaviour and use this knowledge to feed into future network design.

The Challenge

The Geography:

- The North of Scotland has long radial circuits, over very challenging terrain
- Long radial sections of the network are vulnerable to severe weather events
- Upgrading circuits to meet N-1 requirements can be expensive and time-intensive

The Network:

- Rapid growth in renewable generation
- Relatively small levels of flexible demand at present
- Low levels of inherent system stability and strength - particularly, when depleted

Planned Outages for Network Upgrades:

- Upgrade plans for NetZero will involve extensive network outages
- During these times, the network faces increased vulnerabilities
- Scheduling of outages within planned timelines is increasingly challenging

The Risk:

- Faults: Loss of the main link and resultant blackouts
- Curtailed Renewables: Generators are forced to trip off
- Carbon Intensive Back-up: Reliance on diesel stations to restore power

The Ambition

Resilience for Remote Communities

- Reduce risk of large-scale outages
- Faster restoration after outages
- Improve resilience to increasingly extreme weather events
- Overall improve security of supply

Delivering a Network for NetZero

- Reduce costly and time intensive upgrades to very remote parts of the network
- Reduce curtailment of renewable energy generation
- Reduce dependence on back-up fossil fuel generators

Flexibility and Operations

- Autonomous operation of renewable-rich regions
- More options for outage planning and extended network access periods

Unintentional Islanding (Status Quo)

Disrupted. Loss of Mains protection trips all generation. Customers go dark. Circuit remains de-energised for safety.

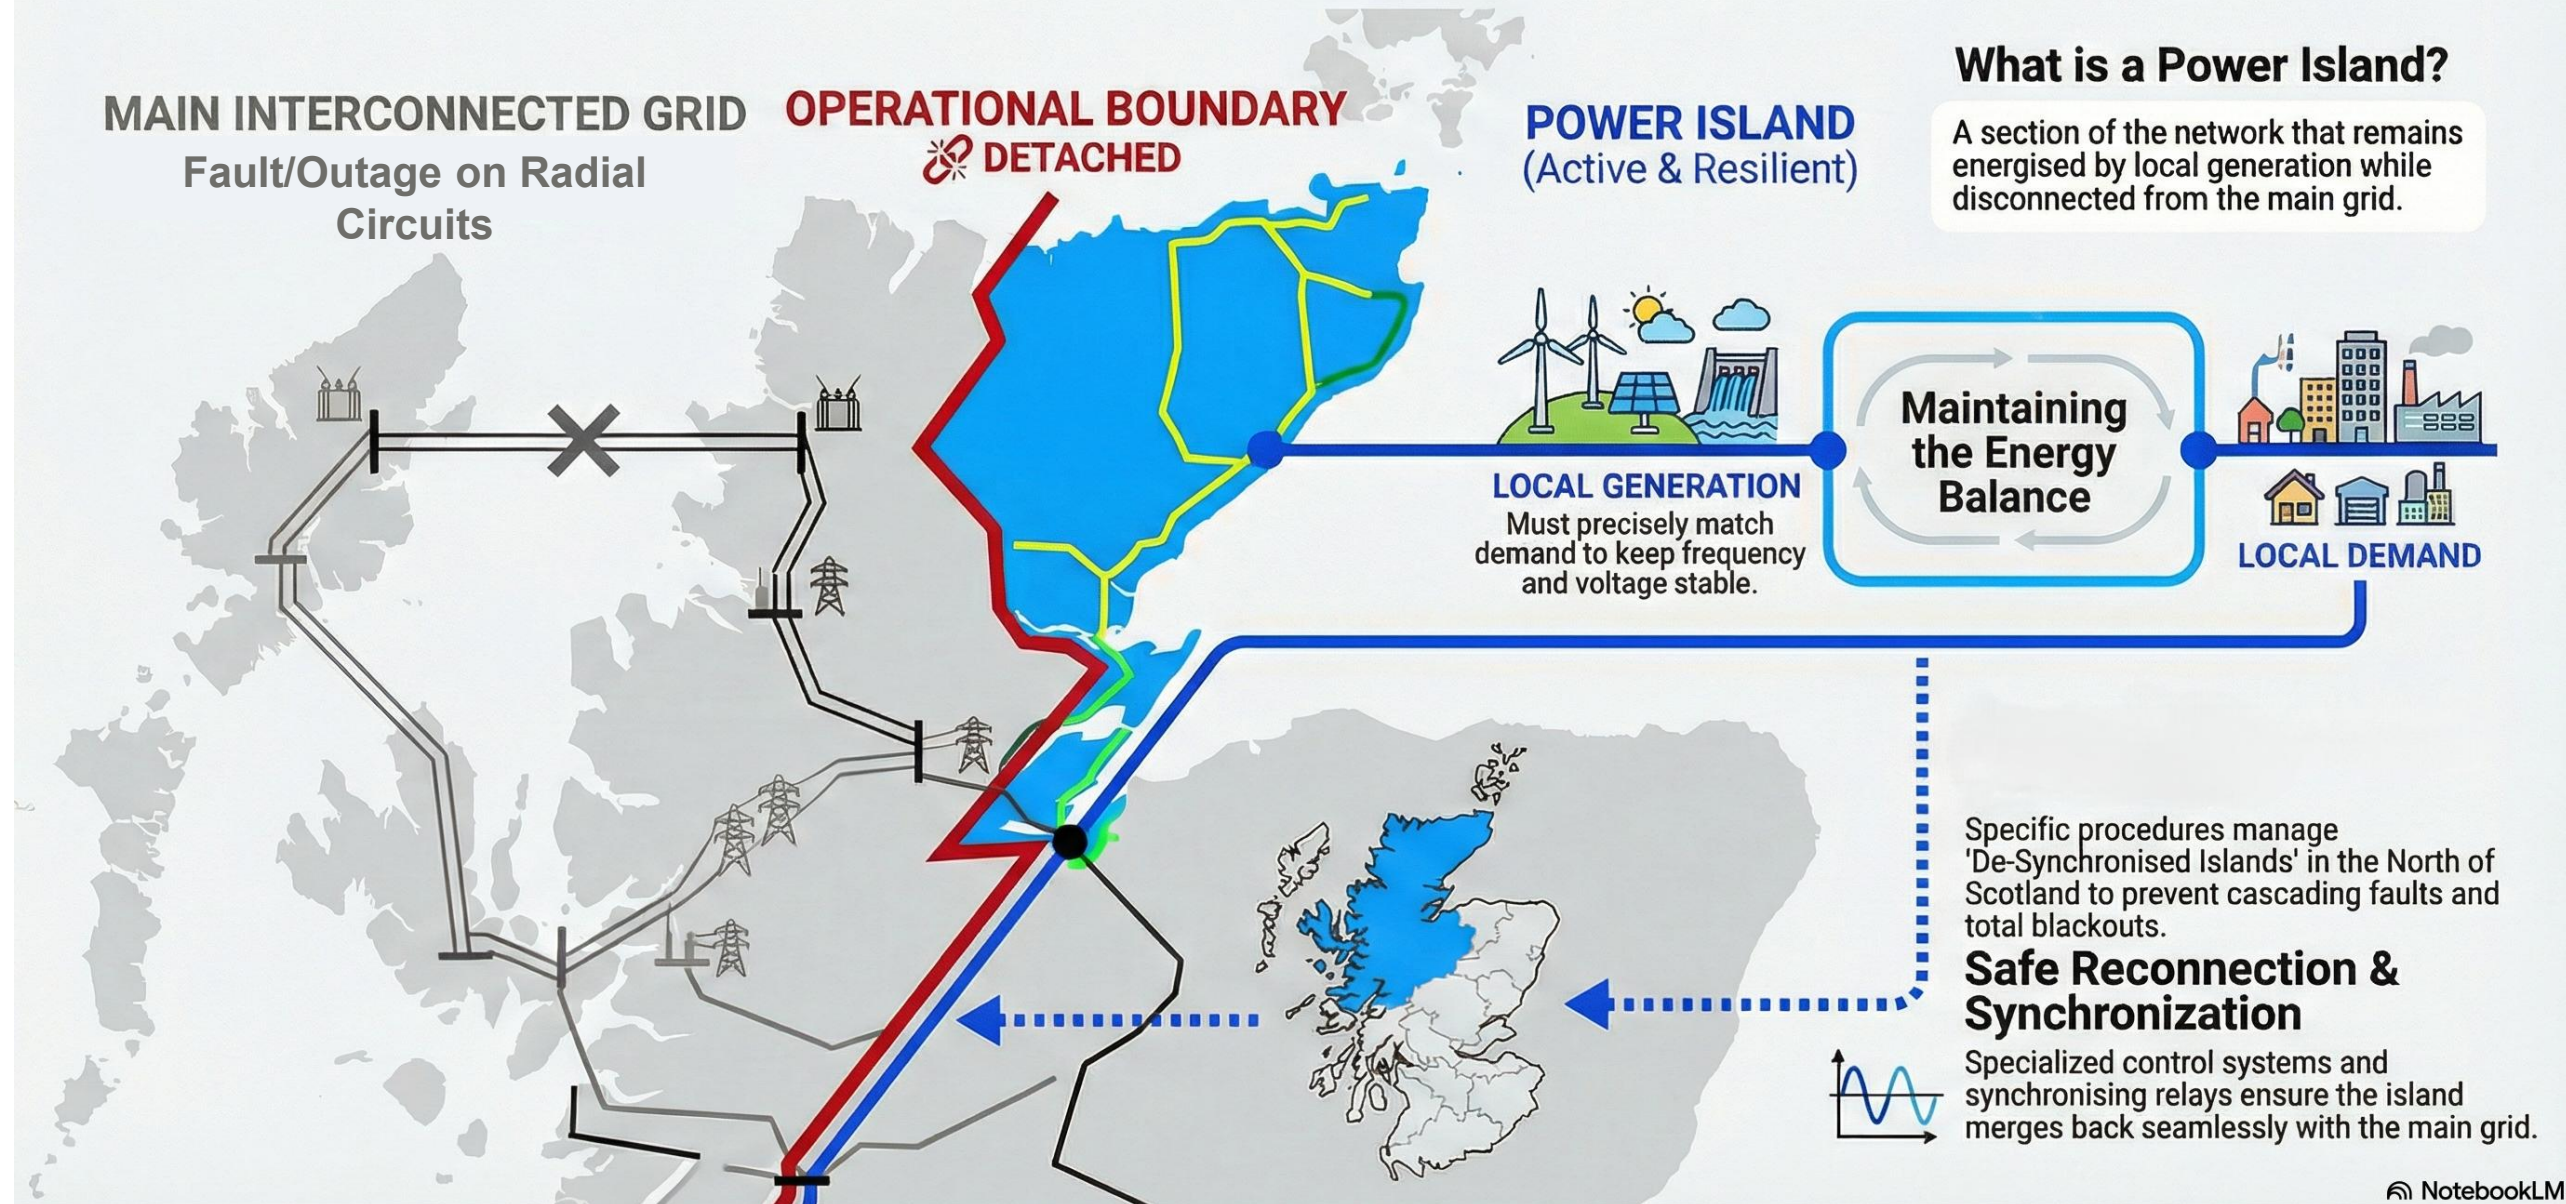

Intentional Islanding (Proposal)

Resilient. System detects fault, opens Point of Common Coupling (PCC), and balances local Generation & Demand. Lights stay on.

The Innovation: Designing for Intentional Islanding

In the **North of Scotland**, vulnerable sections become self-sustaining “Power Islands” to ensure continuous supply during disturbances.

Why is this Innovative?

- Islanding as an intentional network flexibility tool
- Limited GB evidence base for transmission islanding
- High uncertainty around stability, protection and operability of an islanded grid, especially at transmission level
- Relying on renewable energy generation and batteries as anchors
- Regulatory and commercial uncertainties
- **Building-up on Previous Innovation Studies:**
 - WPD Network Islanding Investigation NIA project
 - NESO & SPEN Distribution Re-Start
 - SSEN Project ReFLEX
 - SSEN Net Zero Island
