“

**Intelligent gas grid to enable  
digitalised net zero transition**

”

# The intelligent gas grid

Autonomously and intelligently monitor, control and optimise networks using AI and machine-learning technology and a data-led approach:

**Methane leakage reduction**

**Anomaly detection**

**Green gas injection**

**Hydrogen**

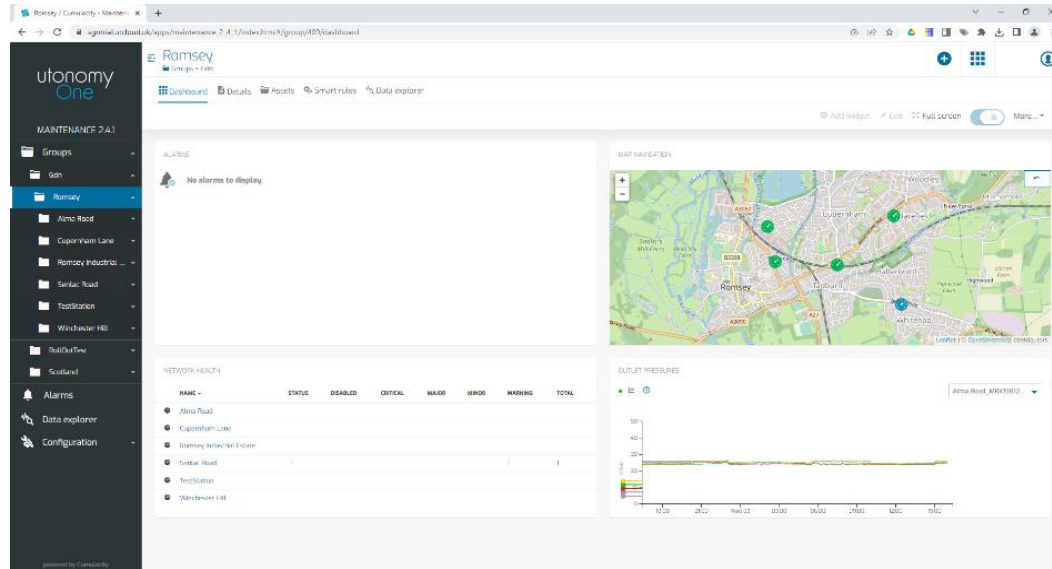

Pressure management with Utonomy

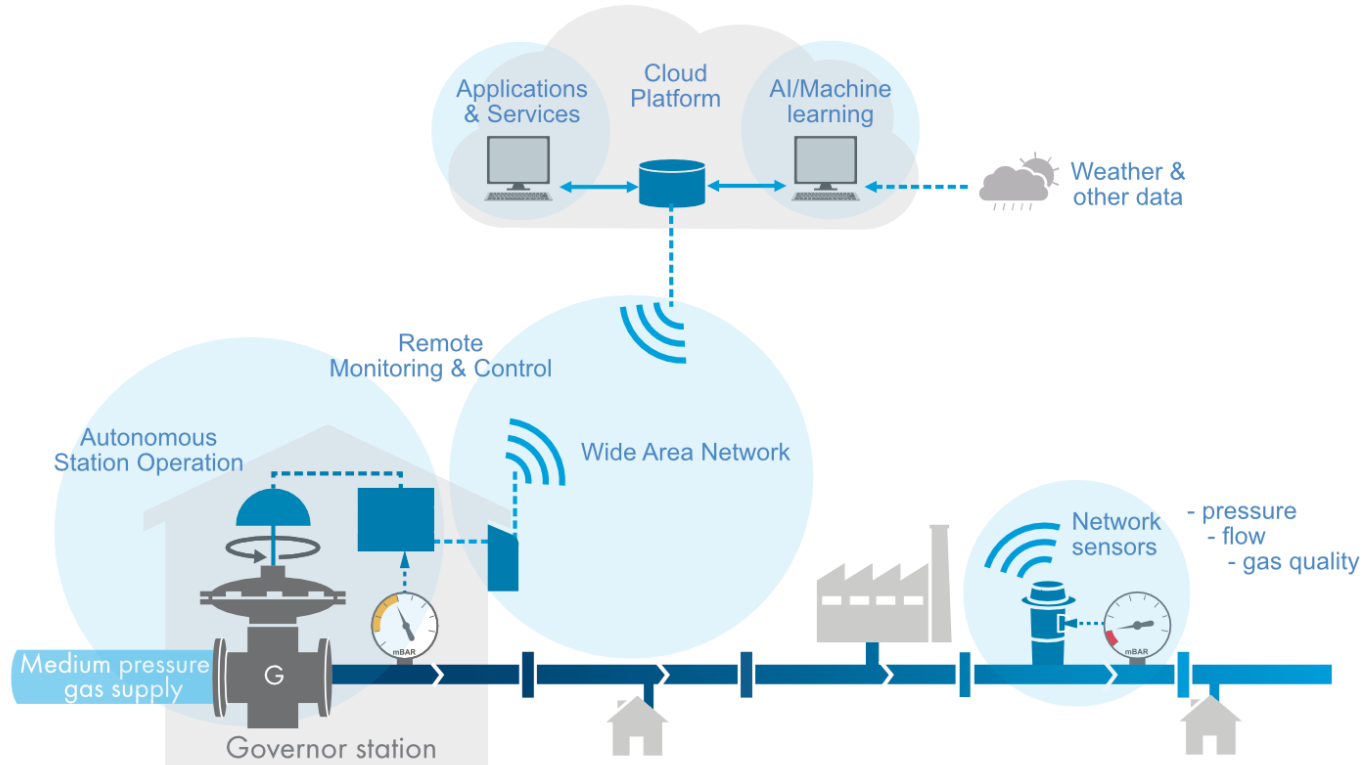

# The background

SGN & Utonomy have collaborated to develop innovative new technology to digitalise the gas distribution networks to reduce methane emissions, increase biomethane feed-in and prepare the networks for net zero

# Intelligent gas grid overview

# Use case 1: Optimising the grid to reduce emissions

Pressure management with Utonomy

## PROBLEM

What pressure should I set each of my governors at to minimise pressure/leakage?

- Demand is changing continuously
- The networks have multiple governors all influencing each other
- No point in the network must be allowed to go below a minimum pressure threshold

## SOLUTION

Machine learning and AI:

- Predictive models forecast demand from a range of factors including weather data
- Machine learning models are created for the network and updated regularly and automatically
- Using both models a schedule of governor set-points is created and downloaded to the governor stations once a day

# Use case 2: Increasing biomethane feed-in

Biomethane without Utonomy

Biomethane with Utonomy

## PROBLEM

Fixed seasonal settings of regulators inhibit biomethane entry:

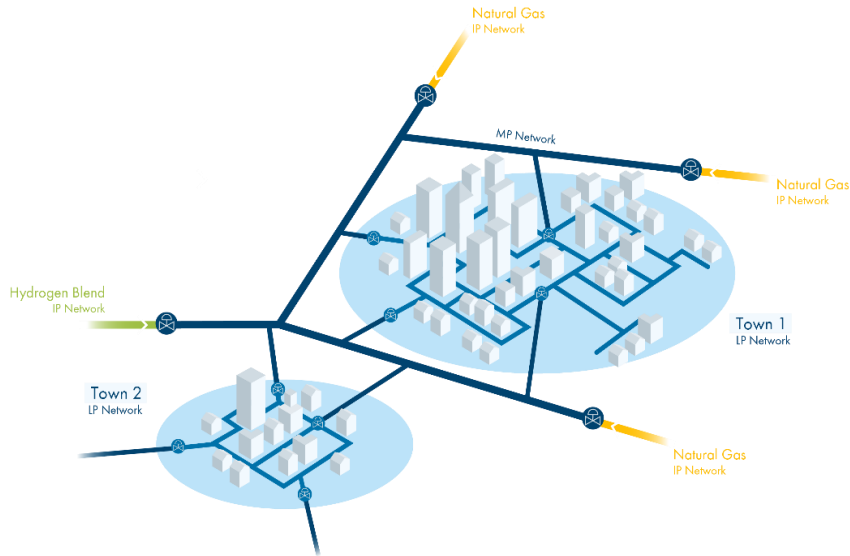

- Artificially high pressures down stream stop injection upstream
- Creates storage constraints at the entry point location
- Potential flaring required to manage

## SOLUTION

Governor pressures are continuously adjusted to the minimum level needed to maintain security of supply :

- Priority of biomethane at all times
- Biomethane plant now able to maximise its feed in
- Network volume can also be used to store surplus biomethane produced overnight

# Summary of Intelligent gas grid benefits

- Reduce methane emissions – 347,000 tCO<sub>2</sub>e\*
- Reduce manual intervention i.e. making seasonal adjustments to governors
- Increase biomethane feed-in capacity – 1.7m tCO<sub>2</sub>e\*
- Improve visibility and management of networks for hydrogen blending and ultimately 100% hydrogen
- Increase efficiency of network operations: detection and diagnosis of network and asset faults

\*SGN/Utonomy IGG SIF Beta project estimates over 10 years for GB

# The pathway

**Initial roll out** in SGN network proves technology and establishes commercial viability

**Rollout to BAU** across the GB distribution networks; initial focus on methane leakage reduction and green gas injection

**Technology evolutions** support CV monitoring and flow measurements in parallel with increasing amounts of blended Hydrogen

**Full digital network** supports sensing and control of dynamic networks and up to 100% Hydrogen
